3 Requirements & Specifications

3.1 Requirements

3.2 Specifications

4 Design Overview & Rationale

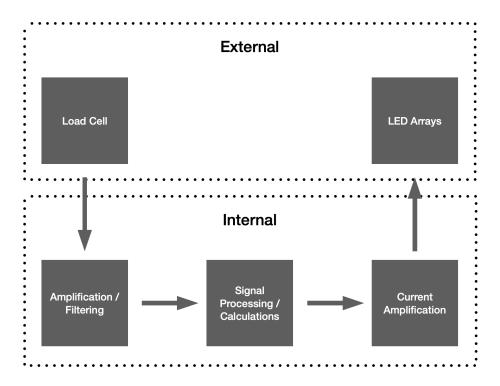

Figure 2: A block diagram of the function of the HeadLight

4.1 Arduino Shield

A load cell is used to measure the force of the head rotation, which has an internal Wheatstone bridge. The output from the Wheatstone bridge goes into an instrumentation amplifier. The instrumentation amplifier consists of non-inverting amplifiers on the output of the Wheatstone bridge, which then goes into a differential amplifier, as shown in figure 3. The output of the differential amplifier goes into an LC low pass filter to remove high-frequency noise.

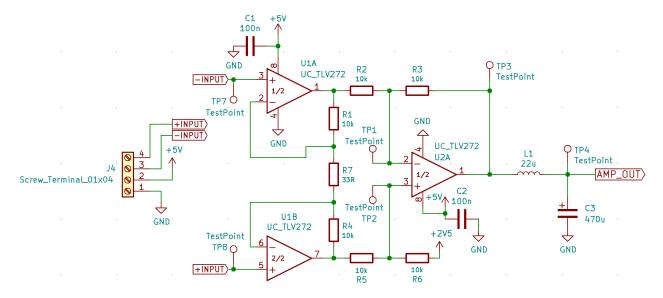

Figure 3: The layout of the instrumentation amplifier.

The output of the differential amplifier can end up being a negative value, as the Arduino can not read negative voltage, and there is no negative supply for the differential amplifier; the differential amplifier has to be biased. A voltage reference was constructed out of a voltage divider of equal values and a buffer to bias the instrumentation amplifier (shown in figure 4).

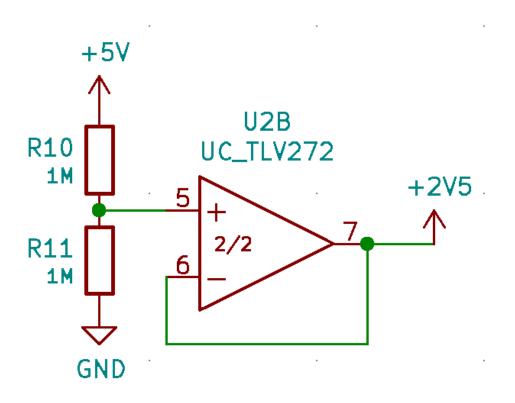

Figure 4: The layout of the voltage reference.

For each LED array, the PWM output from the Arduino goes into the gate of a MOSFET. The current limiting resistor is connected to the anode of the LEDs, and the cathode of the LEDs is connected to the drain of the MOSFET.

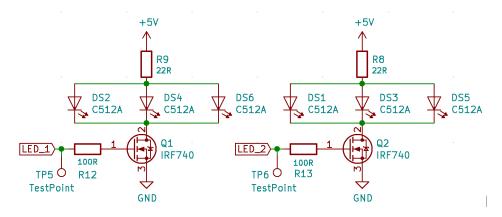

Figure 5: The layout of the LED arrays.

4.1.1 PCB Layout

The PCB was laid out to ensure that the ground plane would have no cuts, maximising EMC performance. Decoupling capacitors were placed right next to the power pins of the ICs. Additional care was taken so that traces were not too close to any antipads, as having traces too close to antipads can worsen EMC [10]. Test points were added so that we can troubleshoot any problems when assembling the prototype. 1x1 header were used as ground test points so that the ground clip of the oscilloscope probe can be attached.

4.1.2 Amplifier

An instrumentation amplifier was chosen to amplify the signal from the load cell. The instrumentation amplifier consists of two non-inverting amplifiers, of which the outputs go into a differential amplifier. As the Arduino cannot read negative voltages, nor is there a negative supply, the differential amplifier was biased with 2.5 V. This results in the positive difference being between 2.5 V and 5 V, and the negative difference is between 0 V and 2.5 V. A one op-amp differential amplifier has an extremely low input impedance; thus the Wheatstone bridge must have a matched impedance. A two op-amp instrumentation amplifier would require one less package but would be less stable than the three op-amp instrumentation amplifier. The three op-amp instrumentation amplifier also has a spare op-amp which is then utilised for the voltage reference.

An initial gain of $24\,\Omega$ was calculated (as shown in equation (4)) [6], but after some test on a breadboard, the gain was changed $33\,\Omega$. This was partly due to the load cell to measure $\sim 50\,\%$ more than rated [4].

$$V_O = \left[\left(\mathsf{Sig}^+ \right) - \left(\mathsf{Sig}^- \right) \right] \left[\frac{R_4}{R_2} \left[\frac{2R_f}{R_g} + 1 \right] \right] \tag{1}$$

$$R_{g} = \frac{2R_{f}}{\left[\frac{V_{O}}{(\operatorname{Sig}^{+}) - (\operatorname{Sig}^{-})} \frac{R_{2}}{R_{4}}\right] - 1}$$
(2)

$$=\frac{2\cdot10\,\mathrm{k}\Omega}{\left[\frac{2.5\,\mathrm{V}}{3\,\mathrm{m}\mathrm{V}}\frac{10\,\mathrm{k}\Omega}{10\,\mathrm{k}\Omega}\right]-1}\tag{3}$$

$$= 24.03\,\Omega\tag{4}$$

4.1.3 Voltage reference

A voltage divider was used to produce $2.5\,\text{V}$ to bias the differential amplifier. It was decided to use a buffer on the output of the voltage divider so that the common-mode rejection error is minimised. This is due to the op-amp's low output impedance, which does not introduce any noticeable common-mode rejection error. A $2.5\,\text{V}$ Zener diode would have been preferred. The resistors in the voltage divider have tolerances and therefore may not give exactly $2.5\,\text{V}$; however, $2.5\,\text{V}$ Zener diodes were not available from the store. $1\,\text{M}\Omega$ resistors were chosen to limit the current and thus power consumption.

4.1.4 Filter

A filter was used to filter out high-frequency noise from the load cell. The filter was chosen to be an LC filter. An RC filter could have been used, but it would have caused the signal's voltage to drop slightly due to the voltage drop across the resistor. The LC filter does require more space on the PCB, but the PCB had enough room for the

capacitor and the inductor. LC filters also have better attenuation as the attenuation slope is twice as steep as an RC filter. The filter was placed on the output of the differential amplifier. If filters were placed on the inputs of the differential op-amp, more components would be needed, and there would not be enough space on the board. A 22 µH inductor was chosen due to its availability in the electronics store. A 470 µF capacitor was selected as a compromise of its physical size, cutoff frequency, and availability. The cutoff frequency was found to be 1.595 kHz, as shown below:

$$f = \frac{1}{2\pi\sqrt{LC}}$$
 (5)
= $\frac{1}{2\pi\sqrt{22\,\mu\text{H470}\,\mu\text{F}}}$

$$= \frac{1}{2\pi\sqrt{22} \text{ uH470 uF}}$$
 (6)

$$= 1.595 \, \text{kHz} \tag{7}$$

4.1.5 LED arrays

Each LED array has a MOSFET; this was done to have enough current supplied to the LEDs. The pins that can output PWM are only able to supply 40 mA, so the outputs from these pins were connected to the gates of the MOSFETs. This allows the LEDs to take full current and are thus brighter. IRF740 MOSFETs were chosen due to their availability in the store and their low resistance. They have a max current of 10 A, so more LEDs can be added if required. The low resistance of the IRF740 $(0.55\,\Omega)$, reduces the power losses when the MOSFET is on. Individual resistors could have been matched to each LED; however, this would increase the number of components and take up extra space on the PCB. $100\,\Omega$ resistors were placed between the PWM output from the Arduino and the gate of the MOSFETs, this was done to minimise ringing and to limit current.

5 **Testing**

The PCB will be assembled and attached to an Arduino. The code will be uploaded to the Arduino. The load cell will be manipulated, and the PWM signal will be probed using an oscilloscope. The duty cycle of the PWM signal will be compared to the expected duty cycle. The LEDs will then be connected, and the load cell manipulated to check that the LEDs behave as expected in terms of brightness and direction changes. The load cell signal will be probed to ensure that the gain resistor is the correct value. This will be done by placing an appropriately 100 g mass on the load cell and measuring the voltage that is output by the instrumentation amplifier.

Conclusions

Appendices

A Applications of the Design Toolkit

Table 1: Applications of the Design Toolkit

Tool Type	Tool Name	Where/How Used
Strategy	Divide & Conquer	Divide and conquer was used to split up the hardware design into: • Instrumentation amplifier
		 LED arrays and driver
		■ 2.5 V reference
		• LC filter The project itself was also divided up so that one person did the software, and the other person did the hardware.
Design Principle	PCB layout	The layout of the PCB was done with the aim of complying with the PCB design rules, e.g. Having components neatly lined up, minimising acute angles of tracks, increasing clearance between components and tracks, and having high current tracks where needed.
Design Principle	Schematic layout	The schematic was done with the aim to follow the layout guidelines, for example, using labels, using power ports, separating major parts of the circuit, and ensuring that the labels are clear and easy to read.
Design Principle / Strategy	Modularity	The code was written with the aim to be modular, e.g. multiple header files and task specific files.
Design Principle	Testability	Test points were added around the circuit to aid in easy testing of the circuit's function.
Strategy	Get another perspective	Both the PCB and the schematic were checked by people other than the designer, such as the other group member and people external to the group.
Building Block	Amplifier	An instrumentation amplifier was constructed out of operational amplifiers to appropriately amplify the signal from the Wheatstone bridge in the load cell.
Building Block	Filter	An LC filter was used to filter out noise from the load cell, and to not attenuate the signal.
Building Block	Buffer	A buffer was used to create a low impedance voltage reference. Buffers were also used on the output of the Wheatstone bridge to provide a high impedance for the Wheatstone bridge so that the signal was not excessively attenuated.
Building Block	Current Limiting Resistor	Current limiting resistors were usd to limit the gate current for the MOSFETs and the current through the LEDs.
		continues on next page

Table 1- continued from previous page

Tool Type	Tool Name	Where/How Used
Building Block	Arduino microcontroller	The Arduino is the main controller for the circuit, it controls the brightness and reads the load cell.
Building Block	Pull up resistor	An internal pull up resistor is used for the button. A pull up was chosen so that the internal pull up resistor could be utilised, keeping the parts count down.
Building Block	Analog input	An analog input was used to read the amplified signal from the Wheatstone bridge of the load cell.
Building Block	Digital output	Digital outputs were used for the MOSFETs that control the LEDs, amd for the auxillary output. Digital outputs are capable of outputting PWM.

43
44
    * Obrief Poll the load cell (by reading the voltage input at the LOAD_CELL_ANALOG PIN)
45
        and compare it to the currently recorded voltage.
     * The methodology for detecting noise is rudimentary, lacking any requirement for the
46
         voltage to remain in a constrained range for a given time, reminiscent of button
        debouncing.
     * A more straightforward method is utilised due to hardware filtering using an active
47
        low pass filter. See shield schematic for details.
